

The accessibility engineer that fixes your code. And proves it.

An agentic workflow that repairs WCAG violations in a website's source, verifies every fix with deterministic re-scans, content-integrity and visual checks, and routes judgment calls to a human - with evidence a business owner can hand to their lawyer.

THE PROBLEM IS A LAWSUIT, NOT A LINT WARNING

5,114

US web accessibility lawsuits in 2025 (UsableNet)

64%

of defendants earn under \$25M - small businesses (UsableNet)

95.9%

of top-1M homepages fail WCAG (WebAIM 2026)

€100k

EAA fines now in force across the EU (per violation, Germany)

The typical defendant is a bakery, a dental clinic, a law firm - a site built by a freelancer in 2019 that nobody has touched since. A manual audit costs \$1,250-\$2,750 and a remediation project \$350-\$550 *per page*: more than these owners will ever spend, so they wait, and one in four ends up sued again.

TODAY'S OPTIONS DON'T FIX ANYTHING

	FIXES SOURCE	VERIFIES	OUTCOME
Overlay widgets accessiBe, UserWay...	no - JS mask	no	FTC fined accessiBe \$1M; ~25% of sued sites had a widget installed
Scanners axe, WAVE, Lighthouse	no - reports only	-	a PDF of problems, still your job to fix
Consultants	yes	manually	\$5k-\$75k per project, weeks of lead time
StepFree	yes - real code	automatically	fixed site + evidence report in under an hour, ~\$2 of compute per site

HOW IT WORKS - AGENTS WITH A DETERMINISTIC SPINE

scan (axe-core) → **route** to five specialist agents (structure · images¹ · forms · ARIA · contrast²) → **verify every fix**: re-scan gate + word-level content integrity + pixel diff localized to the elements each fix may touch → **retry or roll back** what fails → **memory** keeps color and alt-text conventions consistent across pages → **beyond-scanner reviewer** hunts what axe can't see (images of text, fake div-buttons, keyboard traps) → **human review queue** where every judgment call arrives with a drafted fix → **evidence report**.

¹ the image agent looks at every image (vision) before writing alt text. ² contrast fixes come from WCAG math preserving the brand hue. Each design choice answers a documented failure mode of unverified LLM fixes (arXiv:2608.24913; arXiv:2605.27716).

MEASURED ON 12 REALISTIC SMALL-BUSINESS SITES (134 SEEDED WCAG VIOLATIONS)

134/134

WCAG violations remediated & independently verified - 13/13 pages shippable, zero damage

0 vs 8

fabricated image descriptions, StepFree vs the one-shot baseline across two runs (incl. a silenced phone number)

~\$0.50

measured compute per site, vs \$350-550/page manual remediation

32 · 5/5

scanner-invisible issues drafted for human review - all 5 planted traps caught

BUSINESS

- **Wedge**: \$149 one-time "fix & prove" run per site; \$49/mo continuous monitor-and-fix. Agency tier \$499/mo for 20 client sites - agencies hold thousands of 2019-era SMB sites and eat the legal risk conversation.
- **Unit economics**: ~\$2 measured compute per site run → 95%+ gross margin at the wedge price.
- **Market**: digital-accessibility software ~\$1B by 2030, but the spend it replaces - audits, remediation projects, legal exposure across 5,000+ suits/yr - is far larger. Incumbent revenue (AudioEye \$40M, accessiBe ~\$50M) proves willingness to pay for a product that doesn't actually fix code.

WHY WE WIN

- **Honesty as strategy**: automation covers ~57% of issues (Deque). We claim verified fixes for the detectable layer and route the rest to humans - the exact claim discipline the FTC fined the market leader for lacking.
- **Verification is the moat**: anyone can prompt an LLM to "fix accessibility". Shipping it to a stranger's production site takes the guardrail stack - and the evidence trail that survives a legal letter.
- **The curb-cut effect**: curb cuts were built for wheelchairs and ended up serving everyone. Same here: clearer labels, readable contrast, working keyboards - a better site for every visitor.
